Impressive-Gene-421

Are you kidding me? Claude Code found the catastrophe after being asked only to “check for vulnerabilities and thinking for 8 minutes

```
1. ngu.random is wired to a software PRNG, not the hardware TRNG – CRITICAL

There are two independent RNG paths in the firmware, and only one of them reaches the STM32 TRNG.

Path A (correct). ckcc.rng_bytes() → stm32/COLDCARD_MK4/rng.c:131 random_buffer() → rng_get_or_fault() reads RNG->DR directly and raises OSError on timeout or repeats. This is what backups.py:337 uses for the backup-file password.

Path B (broken). ngu.random.* → external/libngu/ngu/random.c:73 CHIP_TRNG_32(), defined at line 24-26 as extern uint32_t rng_get(void).
```

It is unbelievable that some kid with an LLM just stole \$100m+ because no one bothered to check the source code.

That would be Peter Gray, aka `doc-hex`.

The person most clearly associated with the vulnerable Coldcard RNG integration is **Peter D. Gray, via the `doc-hex` account.**

The exact sequence was:

1. `switchk` **, January 28, 2021:** wrote the defective libNgnU feature check.
2. `doc-hex` **, March 1, 2021:** imported that code, disabled MicroPython's hardware RNG in the board configuration, and switched master-seed generation to the affected `ngu.random` path.
3. **Coinkite, March 17, 2021:** released it as firmware 4.0.0.
4. `doc-hex` **, March 11, 2022:** added a reseed API accepting only a 32-bit integer.
5. `doc-hex` **, March 11, 2022:** truncated secure-element-derived hash material to 32 bits and used that API for Mk4.
6. **Coinkite, March 14, 2022:** released the construction in Mk4 firmware 5.0.0.

That is considerably more specific than merely saying "an integration error occurred."

I have a bunch of friends who worked for startups and
this makes perfect sense to me. The world is running
on bullshit (and it mostly works, by the way). I had a
buddy belittled for trying to fix bugs. Gotta move fast
and develop more features! I had a buddy replaced by
AI to do reverse-engineering. He is an insane stickler
for the details and was a huge asset as the rest of the
company does not know how to get into the weeds like
him.

The unfortunate reality is that this attitude might be
profitable. Don't take one catastrophe as proof that it
doesn't work. Think about all the shitty products that are
out there that are making bank or get acquired.

complimenting Claude... it's commentary on how fucking stupid ColdCard is and how they clearly did not test their RNG device sufficiently. This entire story is a nothing burger if you used your own RNG methods to generate seed phrases.

HollaWho • 1d ago

I work in IT and vulnerability remediation is part of my role. The last three months have seen record amounts of CVEs month after month. AI is giving so many threat actors tools to quickly identify vulnerabilities. We're getting hammered

cyclism- • 1d ago

Exactly, patching overload right now!

1 more reply

shedeghog-orchard • 1d ago

I do just want to highlight the fact that yes it could be that AI is just finding a lot of bugs we couldn't before, but I also am a full time SW engineer and I'm more and more seeing the shittiest software I've ever seen be shipped because it's vibecoded and the engineer who generated it barely checks it over, which could also contribute to a higher amount of CVEs

Aazimoxx • 23h ago

You don't get CVEs for software no-one's using though, and a lot of vibecoded slop is either dead in the water (app store noise) or bespoke stuff used by an individual, family, group or club, or single company mostly internally...

If a company has decent review procedures, these can only be enhanced by modern LLMs, not hurt - unless those procedures get bypassed, which is the real problem.

1 more reply

HollaWho • 23h ago

That's absolutely part of it. AI is a double edged sword as far as vulnerabilities go. And

tough lol

ColoradoStudent • 21h ago

Same, man. We've never been busy like this before. WordPress is getting wrecked.

JustSkillfull • 21h ago

I feel like my whole company, especially my org core platform who owns 100's of different services from 3rd parties + some custom in-house projects has turned from software engineering delivering features to the robot from Rick and Morty who's sole purpose is to pass the butter but patch the images.

Recently (12 or so months) it's moved from 20% KTLO (patching / fixes) to 70% KTLO. We've moved to more secure base images from a 3rd party hardened paid image repository, and constantly behind SLOs since we were a Federated US Gov programme we have very strict SLO handling and exception processing.

Some weeks it's just patching. 60 images all need patching, tested, and deployed. Fun.

-

jungle • 19h ago

Ah yes, fedramp must be a nightmare right

habbadee • 1d ago

Let's imagine Coldcard learned this bug was out there in the wild. What do they do about it?

Obviously they issue a firmware patch, but how do they get people to apply it and generate new seeds without alerting the world of the flaw and the fact that bad actors can determine seeds?

They can't notify owners of the devices. They can't announce the reason for the firmware fix when telling people to apply it and generate new seeds. Once the bug was out there and vulnerable seeds generated, they were well and truly screwed because fixing it would announce its existence.

+ 1 more reply

Kine7ic • 23h ago

Great point. I haven't seen anyone bring that issue up before. I assume they would put out a generic warning about certain firmware versions and send that to their email list. But then users would still need to move to a new address made by the new firmware to be protected. Hardware wallets need to be perfect from release with critical systems like their seed generating code. Once you find a flaw this deep it would be a disaster for a company to tell everyone to make a new wallet address.

No-Contribution23 • 21h ago

true, it would be a disaster, but still better than what actually happened.

announce they are shutting down operations and wont be continuing to update their products while telling customers to migrate to a new company.

This would kill their business overnight but at least people wouldn't assume there's a vulnerability and the majority would transfer.

Idk, it's a tough one.

llnsulince • 17h ago

People would migrate without changing their seed. They'd simply import it. That's not sufficient.

Mallmagician • 22h ago

Maybe their only option is to drain those wallets themselves using the vulnerability. Then return them to the original owners once the funds are secured and the original owners have secure wallets again.

Rannasha • 22h ago

How do you identify the original owners? The standard method of proving address ownership (signing a message with the private key of the address) isn't usable since an attacker can crack the seed using the vulnerability and provide proof of address ownership.

3 more replies

1 more reply

llnsulince • 17h ago

This is exactly why I believe it's more likely that they did know about this bug, and for how much I loathe them for putting the people who did the best they possibly could for their stack, I do have trouble blaming their "inaction". Their hands are tied in a cruel joke that the very act of trying to fix it makes the problem immediately worse.

Action is damaging in this case because attackers move far faster than customers. As soon as any kind of announcement is made, the attacks are in full swing. Therefore, it may be "best" to just stay quiet. I mean... man I mean I don't know what's best in this scenario. There's no way to move anyone without revealing the problem to everyone. The best I can think of for taking

without stating why or what the cause was. This would alert attackers that “something” is wrong, but not specifically what... still I think attackers would act quickly and find it before the majority of customers can escape to secure keys.

I just think that when faced with the idea that the security-first and leading hardware wallet company never once, over 5 years, tested the execution path of their device to actually generate truly random numbers, arguably the only job of the entire device, I have trouble accepting that. It's a level of incompetence so ridiculous that it makes me think conspiracy is more likely. But more likely than even that is that the DID realize, but then further realized in horrr that they *cant* act, lest they make the problem 10x worse immediately.

Idk, I guess it's more likely they're actually just that incompetent, but holy hell that's such a massive L. Fuck CoinKite.

EconomyDoctor3287 • 16h ago

Doing nothing just means an attacker has time to prepare a plan before acting on it

dondondorito • 1d ago

Yeah, this is what I expected. The fact that a massive critical bug was exploited shortly after the release of Fable was highly suspicious.

This sort of thing will happen more often now. It is extremely unsettling that the developers didn't test their code with Fable, after Anthropic released it.

magicmulder • 1d ago

I would bet an older model would have found this as well. At least since 4.6 Opus, Claude has been very good at discovering such flaws as “if this condition applies, the code silently falls back to a less secure approach”. I get this all the time when auditing code with those models.

This case is not some crazy godlike “no human would ever have found this” (like when that guy hacked the

shedgehog-orchard • 1d ago

I was just gonna say. All this talk about AI, they did not need AI to detect this error 🧑 for all we know the hacker could have discovered this themselves without AI it's such a massively stupid fuckup on the ColdCard

wentwj • 1d ago

it's immensely surprising to me this wasn't caught without AI and wasn't exploited years ago. This is basically the textbook thing you'd look for in "is this hardware wallet secure". You'd look at how it does its key gen and if it's doing something stupid there, not using true random being one of the main things it could do wrong there

shedgehog-orchard • 23h ago

Completely agreed! I have no evidence to suggest this but just trying to think like the hacker, they could have even discovered this years ago but waited for the ColdCard to gain traction and/or see if anyone would discover it first. Probably unlikely given the patience required but it's possible they could've been sitting on this for years and we may never know.

2 more replies

1 more reply

Crypto-Guide • 1d ago

I actually had a few models review the coldcard codebase over the last year and none of them found this issue.

I have been testing a few things and basically most LLMs will find it if you give them a specific prompt to look for this specific type of bug, but it's only the frontier models (like Kimi k3) that will find it on their own.

EdmundTheInsulter • 1d ago

used and applied every tool correctly. On top of that there are truly stupid people around, you only need one totally weak link.

I experienced endless cases where people couldn't back up and secure databases, for example thinking that disk redundancy was a 'backup', which it wasn't if the whole machine was destroyed, but what actually happened is that the redundant disks failed without them knowing until too many failed - total incompetency, but the people just stayed at the company etc.

Issue 2 was a guy who had a website, he was backing up his large database onto his copy, but while he was backing it up, his database failed whilst overwriting his only copy - he was actually that stupid and too stingy to have equipment to backup his backup, or even foresee that total failure scenario (all avoidable in 1001 ways), like the first one, they couldn't foresee the machine in one room could catch fire

nullc • 18h ago • Edited 18h ago

🏆 Top 1% Commenter

It's more subtle in the code than you might be giving it credit for.

They disable the built-in TRNG wrapper to replace it with their own version that was more sensitive to unexpected behavior (maybe too sensitive, but that is another issue...), but the code that triggered their replacement was done in an inconsistent way that caused it to not actually get enabled.

This is because the micropython code disables the TRNG when `MICROPY_HW_ENABLE_RNG` is 0 but the replacement code tests for `MICROPY_HW_ENABLE_RNG` being defined at all, and if it is set to zero it is still defined. If both modules checked the value or if both modules checked for definedness then the behavior would have been correct (or would have failed to compile). Because of the inconsistency the TRNG was replaced by an insecure PRNG that still behaved in a way that appeared and would test as correct.

shaped and doesn't actually engage with the handle when connected, leaving you with no breaks. But from a quick glance it looks like one set of breaks were disconnected and another set connected.

magicmulder • 18h ago

You explained correctly, they tried to replace code with their own implementation. And then didn't test whether that code was actually executed. Sorry, that is below junior dev level in my book. That is "gets you booted during your trial period" stuff.

nullc • 18h ago

 Top 1% Commenter

Yes it should have been caught with defensive development at the time it was authored, it might have been caught if someone had tried to port the code to another platform.

I guess my comment was more zeroing in your "no human would ever have found this" remark-- to note that one the error was made it was actually a subtle one.

A lot of comments on reddit right now are basically saying "look they disabled the RNG, of course it was broken, how could anyone have missed it!" but short of debug instrumenting the replacement (which should have been done at development time) or analyzing the binary to learn that the path that accessed the hwrng was dead (or even omitted by the compiler) it is actually tricky to spot.

Can someone do this on Trezor code and see what Claude says?

Major-Front • 23h ago

If they did and found something do you think you'd still have your bitcoin lol

FigAggressive237 • 22h ago

Yes he could have, why are you assuming that?

This hack in particular lowers the seedphrase's entropy from 2^{128} , to 2^{40} and 2^{72} depending on the firmware, but this is an upper bound I believe

If its remotely close to 2^{72} , its still safe-ish. I do think that each guess requires PBKDF2-HMAC-SHA512 (2048 rounds) plus elliptic-curve point derivation to check if it produces the target address.

na3than • 23h ago

👤 Top 1% Commenter

If you're trusting a vendor's statement about how their product works you've completely missed the point of the ColdCard incident. Coldcard mk4 and Q were also supposed use multiple sources of entropy when generating the seedphrase. The problem isn't that ColdCards was insecure by design; the problem is that a change introduced long after the secure system was designed and implemented inadvertently bypassed one of those sources and their test protocol wasn't sophisticated enough to detect it.

Coinkite would have said the same thing prior to the attack. Coinkite *believed* their firmware was generating 128 bits of entropy from the device's TRNG and two secure elements.

+ 1 more reply

Indyxc • 17h ago

Hate to say it,, I love BTC, and used to store all of it on cold storage (ledger), but decided to move it to Fidelity when Ledger started scheming with back up recovery options. Not my keys, not my coin sure, but if Fidelity goes under, with 18T AUM, the only thing worth money will be fuel, bullets, guns, and food.

+ 1 more reply

PeterZ4QQQbatman • 1d ago

This morning I tried to reproduce the Coldcard RNG bug discovery process.

I checked out the repository at commit 37e4af5 (May 2021) and gave the code to some AI models for a security review.

Composer 2.5, Grok 4.5 High and GPT-5.6 Luna High. None of them found the bug even after telling them to check the code that generate a new wallet. Nothing.

Note. I had to explicitly tell them not to search the internet, because Grok 4.5 found the bug after checking GitHub.

+ 1 more reply

-5H4Z4M- • 1d ago • Edited 20h ago

Irony is that you hear everywhere that "This shit is 100% secure because it's 100% open source", but "open source" just means the code is available to be checked by anyone....and it wasn't.

edit : Guys before jumping on me saying it was source visible only (which i know) , please read again the part where i intentionally put quotation marks to describe what WE HEAR EVERYWHERE. This are not my words but what you mostly see on forums even from IT people. My post was actually the point of showing that people mix everything together.

Just like the math proofs that were found over the last weeks, that no person has found until now and thus couldn't have talked about online?

This is a community about a technology that has revolutionized assets and financials in many ways, laughing about the people who pushed back and doubted them. And now the people supporting new technology do the same thing when it comes to AI. Can't make this shit up... The circle of life...

If you think that's the level of AI you are still living in 2023.

As an electrical engineer working in a firmware/software role. I would guess this hardware wallet was made by a computer science engineer.

"Oh this is easy! *Does 0 research.* Grabs a popular chip and installs some libraries off git. Call this function and call that function and bam. There it is, the final product and it only took me a few days to make!"

What do you mean TRNG? What's that? I don't need it! See it works fine! Entropy? What's that? I called Random(), so the result must be!

Impressive-Gene-421 **OP** • 1d ago

Even worse haha, it was "call this function and call that function and huh, it doesn't compile, I'll just set this to 0, now it compiles bam!" (seriously)

Aggravating_Stage996 • 1d ago

Funny thing is with this IC they even give you premade functions packaged with a pretty nooby GUI to configure the hardware. It's awful but it's enough to demonstrate the isolated capabilities of the chip. It seems even just copying that tool generated code and gluing it to theirs was too much hard work for them!

Express_Living2264 • 1d ago

tbh. that's how a playstation got hacked. the rng function always returned 0 iirc.

science degree.

When you get a computer science degree you will learn that computers are deterministic. You will learn that even with “AI” you cannot achieve true randomness unless you have a physical entropy source.

Most computer science degrees will spend considerable time discussing randomness. Just off the top of my head randomness (and pseudorandomness) were at least mentioned in Discrete Mathematics, Probability and Statistics, Algorithms, Data Structures, Computer Security, Cryptography, Operating Systems and Distributed Systems.

We spent an entire section in probability and stats of how difficult it is to produce true randomness.

You can’t get through a reputable CS degree without having at least a good grasp on how difficult it is to achieve true randomness with a computer

Yeah the “testing” that they did was something I’d fire a junior dev for. Proper testing does not just check for some flags, it validates that the expected functions are called, and the functions we absolutely don’t want called are not called. Which includes a “fallback to a weaker approach”.

cgimusic • 20h ago

I’m kind of curious why they didn’t have it tested by one of those companies that certifies gambling machines. Auditing RNG is basically their entire job.

While cold card fucked up big time, it’s easy to point a tool at a known problem and tell it to find the problem in hindsight.

Finding the problem before others were aware it’s a problem is a different story.

But still fuck, this is gonna set us back years

...to find the problem in hindsight.

Bruh. Prompt was literally "check for vulnerabilities".
Let's not break our backs trying to bend over too much
for the million dollar+ companies.

This sort of adversarial AI code review (before each
release) should be a mandatory checkbox for business
liability insurance, like having annual smoke detector
checks in a building.

Does anyone remember a month or two ago when the feds
had a meeting with certain large companies to tell them that
AI found some really troubling shit really quickly and they
need to make preparations ASAP?

Pepperidge Farm remembers....

This was def preplanned and in the works for quite some
time, since attackers knew that draining the wallets will alert
everyone and once they start they will be in the race against
time. But I agree with the part that someone with little to
none knowledge could have also performed this attack,
probably even attempted once the news was out.

asml84 • 1d ago

I'd even argue the original attacker is currently
competing with other (secondary) attackers.

circumcisingaban • 1d ago

thats what i was wondering

verbose mess.

Aazimoxx • 22h ago

Excerpts from my own global instructions, hope they help:

Respond very concisely by default; interaction with the user should comprise short, high-information outputs unless expansion is requested.

Be constructively critical when it improves the work, and **avoid performative agreement or disagreement**. Flag material risks, weak assumptions, and unsound technical choices when they may harm correctness, maintainability, safety, or outcome quality; give **concise** reasoning and a practical better path.

Before adding or expanding instructions, review related existing instructions and **prefer the smallest effective refinement**.

The bits I've bolded here definitely tend to make a meaningful difference to unnecessary verbosity, with the last one helping massively to cut down on instructions bloat.

it is easy if you know where to look - hindsight bias; But yeah it is a big oversight nonetheless I concur

10nmTransistor • 22h ago

Sometimes I wonder, what all other vulnerabilities are out there in other important open source codes. Gives me goosebumps.

Zealousideal-Bug1837 • 15h ago

It's not that this stuff is difficult. It's that it's basically day 0 and it's becoming automated more and more.

This is basically showing that all this idea of open source is secure because community audit it.. is f\$\$ing bullshit. That would have been found by anybody with some skill that decided to look into it, but nobody did it in years... In other words, Everybody's business is nobody's business
